1 Workshop Schedule

11:00 - 12:00 Overview of GLV
12:00 - 1:00 Code examples
1:00 - 2:00 Lunch
2:00 - 3:00 Build GLV
3:00-4:00 Modify GLV example(s)

2 GLV Overview

GLV (Graphics Library of Views) is a GUI building toolkit written in C++ for Linux, OSX, and Win32. GLV is specially designed for creating interfaces to real-time, multimedia applications using hardware accelerated graphics. GLV has no dependencies on other libraries other than OpenGL which is provided by all modern operating systems. Although windowing is technically not a part of GLV, it does provide an abstraction layer for creating bindings to a particular windowing system for creating an OpenGL context and getting mouse and keyboard input. A binding to GLUT is currently provided.

2.1 Related Work

The following are other cross-platform C++ GUI libraries that use OpenGL for rendering:

3 Obtaining and Building

The GLV source code can be downloaded from
http://mat.ucsb.edu/glv/

or checked out through SVN here
svn co https://svn.mat.ucsb.edu/svn/glv-svn
3.1 Linux Compilation

The simplest way to build the library is to use GNU Make (see section 2.4 below). Use either Synaptic or apt-get to install the most recent developer versions of GLUT and GLEW.

3.2 Mac OS X Compilation

You can build the library using either GNU Make or Xcode. If you are using Make, see section 2.4 below. To use Xcode, you will need to install the developer tools from Apple. You can get them for free (after registration) from http://developer.apple.com/. The Xcode project is located at osx/GLV.xcodeproj.

3.3 Windows Compilation

You will need to either use Cygwin or MinGW with GNU make or create a new Visual Studio project. Visual Studio Express can be downloaded for free from Microsoft. Neither of these two methods have been tested, so you can make a contribution to GLV if you come up with a working solution.

3.4 Building With Make

If you had to install Make, test that it is working by opening a terminal and typing ‘make –version’. Before running Make, ensure that the correct build options are set in the file Makefile.config. These can be set directly in Makefile.config or passed in as options to Make as OPTION=value.

To build the GLV library, simply run

```
make
```

and hope for the best.

4 GLV API

4.1 Core Objects

Rect

Rect is a geometry base class that all Views inherit from. It represents a rectangular object with data members to describe its position and extent in pixels. Its position is stored as the coordinate of its top-left corner on a cartesian grid with positive x going right and positive y going down.

A Rect can be constructed in the following ways:

```
Rect r1(10, 5, 100, 50);     // position (10,5), dimensions (100, 50)
Rect r2(100, 50);            // position (0,0), dimensions (100, 50)
Rect r3(100);                // position (0,0), dimensions (100,100)
```

Rect has methods for changing its position and extent and multiple methods for getting its right edge, bottom edge, center points, area. There is also a method to determine whether the Rect contains an x-y coordinate. This can be used, for instance, to check if a Rect has been clicked on in the window.
View

A View is a Rect that has a drawing routine, methods for responding to various events, and properties for being a node in a tree of Views. Every View has a virtual onDraw() method that gets called every frame. This method contains the View’s specific OpenGL commands to display it on screen. A View contains four View references, parent, child, left sibling, and right sibling, that enable it to be a node in a tree structure. This is the main basis for how Views are organized spatially and behaviorally within a top-level View. Views are rendered by traversing the View tree pre-order calling each View’s onDraw() method, starting at the root View.

The code to produce the hierarchy shown in Fig. 2 is as follows:

```cpp
// Create the Views
View v1;  // top parent
View View v11, v12;  // 2nd level
Views View v121, v122;  // 3rd level Views

// Create the tree hierarchy
v1 << v11 << (v12 << v121 << v122);
```

The << operator adds its right operand as a child to the left operand. The operator returns the parent view, so that multiple children can easily be added using method chaining.
The **View** class has the following enumerated property bit flags:

- **Visible** // Whether to draw myself
- **DrawBack** // Whether to draw back rect
- **DrawBorder** // Whether to draw border
- **CropChildren** // Whether to crop children when drawing
- **CropSelf** // Whether to crop own drawing routine(s)
- **Focused** // Whether View is focused
- **FocusHighlight** // Whether to highlight border when focused
- **HitTest** // Whether View can be clicked
- **Controllable** // Whether View can be controlled through events

The properties can be interfaced to through several methods:

```cpp
View v;
v.enable(Visible); // enable a property
v.disable(DrawBack); // disable a property
v.enable(DrawBorder | CropSelf | HitTest); // enable multiple properties
v.toggle(Visible); // toggle a property
v.property(DrawBack, true); // set property using a boolean
if(v.enabled(Visible)){...} // check if a property is enabled
```

A **View** can also reposition or resize itself automatically when its parent resizes. These capabilities are controlled through its **anchor()** and **stretch()** methods. In the most general case, anchor and stretch factors can be specified in each dimension as floating-point values between 0 and 1. The factors determine how much of the parent’s resize amount is added to the view’s position and extent. The following figures illustrate how a child view (C) behaves when its parent (P) is resized by dx and dy.

![Resize behavior with various x, y anchor factors](image-a)

![Resize behavior with various x, y stretch factors](image-b)

**Figure 3**

**GLV**

The **GLV** class acts as a top-level **View** as well as a bridge to a windowing system. This class handles the drawing of the **View** hierarchy and distributes mouse and keyboard events from the window to its descendents. A **GLV** object is usually constructed with a static drawing callback.

```cpp
void drawCB(View * v) {
    // v is a pointer to a GLV
}
```
The **GLV** class contains objects with the current keyboard and mouse state that can be accessed from event and drawing callbacks.

**Place**

**Place** is an enumeration namespace for specifying specific points on a rectangle. The defined types are TL, TC, TR, CL, CC, CR, BL, BC, BR where T = top, B = bottom, L = left, R = right, and C = center. These are primarily used for positioning views and specifying parent anchoring points.

**Direction**

**Direction** is an enumeration namespace for specifying a direction. The defined types are N, E, S, and W. The convention used in GLV is that north points to the top of the screen and east to the right of the screen. **Directions** are used primarily for specifying the placement flow of layout managers.

![Place and Direction enums](image)

**Figure 4: Illustrations of Place and Direction enums**

**Color**

The **Color** class stores colors as their constituent red, green, blue, and alpha (RGBA) components. **Colors** can be created in several ways:

- Color c1(0, 1, 0); // green (alpha = 1)
- Color c2(0, 0, 1, 0.5); // blue with alpha
- Color c3(0.5); // grey scale

There is a lightweight HSV struct defined to allow working within the HSV color space. **Colors** can be constructed with this alternate syntax:

- Color c(HSV(0.5, 1, 1)); // create a new color from HSV values
- c.print(); // prints [0.00 1.00 1.00 1.00]

Likewise, we can set and get a color’s HSV values:

- Color c; // create a new color
- c = HSV(0.5, 1, 1); // set its RGB components from HSV values
- c.print(); // prints [0.00 1.00 1.00 1.00]
- HSV h; // create a new HSV struct
- h = c; // convert color’s RGB components to HSV
- printf("[%g %g %g]", h.h, h.s, h.v); // prints [0.5 1 1]
HSV also has a special constructor to allow a short-hand method of getting a color’s HSV values.

```cpp
Color c(HSV(0.5, 1, 1));
HSV h(c); // create a new HSV struct from a color
printf("[%.0lg %.0lg %.0lg]", h.h, h.s, h.v); // prints [0.5 1 1]
```

**Style**

The Style object contains properties that determine the look of a View. Each View contains a pointer to a single Style object. By default, this is set to the global Style object Style::standard().

```cpp
View v1;
v1.style(); // reference to Style::standard()
v1.style().color.back // the background color
v1.colors().back    // shorthand for style().color.back
```

**Window/Application**

The Window class provides the actual operating system window for drawing OpenGL. There are currently only bindings to GLUT, but others can easily be created by subclassing Window. The Window holds a pointer to a GLV context. The code for setting up a Window typically looks like this:

```cpp
GLV top(drawCB);
Window win(800, 600, "GLV Window", &top);
```

The Application class is responsible for starting the main application event loop. Application::run() is called after setting up the GUI code.

**Keyboard**

This is a class used to store the current state of the keyboard. The state includes the key code of the last key pressed, whether it was pressed or released, and the state of modifier keys shift, control, and alt.

Printable keyboard keys can be referenced by their non-shifted ASCII character. For non-printable keys, there exists a Key::t type with the following types:

```cpp
Enter  F{1-12} PageDown
BackSpace Insert PageUp
Tab     Left  End
Return  Up    Home
Escape  Right Down
Delete  Down
```

Here is a skeleton code illustrating how to map key events to various actions, such as inside a callback:

```cpp
switch(keyboard.key()){
    case 'b': break;
    case 'c': break;
    case Key::Escape: break;
    case Key::F5:  break;
}
```
Mouse

This is a class used to store the current state of the mouse. The state includes its buttons' state, coordinates relative to the window, coordinates relative to its listener, coordinates relative to the window when each button was pressed, mouse wheel position, and velocity and acceleration in the x and y directions.

4.2 Messaging

There are two message passing subsystems in GLV— default GUI event callbacks and customizable notifications between objects.

Event Callbacks

A View can handle callbacks through virtual methods and/or function pointers. Upon receipt of an event, a View's virtual methods are called, then its list of function pointers, if populated. A View can receive any of the following events of type of Event::t:

- Quit
- FocusGained
- MouseDown
- KeyDown
- FocusLost
- MouseUp
- KeyUp
- MouseMove
- KeyRepeat
- MouseDrag
- MouseWheel

A View’s virtual methods are:

```cpp
virtual void onDraw();
virtual bool onEvent(Event::t e, GLV& glv);
virtual void onResize(space_t dx, space_t dy);
```

The function pointer types are:

```cpp
typedef bool (*eventCallback)(View * v, GLV& glv);
typedef void (*drawCallback)(View * v);
```

Virtual methods can be overridden by subclasses to customize their behavior. The following example shows skeletal code for a View subclass defining its own callbacks.

```cpp
class SubView : public View{
public:
    virtual void onDraw(){
        // drawing commands within local pixel space
    }

    virtual bool onEvent(Event::t e, GLV& glv){
        switch(e){
            case Event::MouseDrag: return false;
            case Event::MouseDown: return false;
            case Event::KeyDown: return false;
            }
        return true;    // bubble unrecognized events to parent
    }

    virtual void onResize(space_t dx, space_t dy){
        // dx and dy are the changes in dimensions
    }
};
```
A View also has a single pointer to a drawCallback type and a map of eventCallback lists. A View’s function pointer type callbacks are called after its virtual callbacks. The event callbacks are special in that one or more can be added per event type. View has an overloaded, chainable function operator defined to simplify appending event callbacks.

```cpp
View view;
// append mouse dragging behaviors to view
view (Event::MouseDrag, mouseMove)
  (Event::MouseDrag, mouseResize);
```

**Notifications**

All GLV Views inherit a Notifier class so they can operate as the subject of one or more observers. The principle of operation is for a Notification object to be passed from the sending object (subject) to the receiving objects (observers). The Notification holds pointers to the sender, receiver, and optional data and is handled by a user-defined callback function. This is used primarily for sending out notifications when a widget changes its value. For instance, we may want to update a label according to the value of a slider:

```cpp
// Notification callback
void sliderUpdateLabel(const Notification& n){
  Label& l = *(Label *)n.receiver();
  Slider& v = *(Slider *)n.sender();
  l.label(v.valueToString());
}
```

```cpp
int main(int argc, char ** argv){
  Slider slider;
  Label sliderLabel;
  // Notify the label whenever the slider value is updated.
  slider.attach(sliderUpdateLabel, Update::Value, &sliderLabel);
}
```

All widgets have specific ChangedValue types that are sent with the notification. A ChangedValue holds a generic value type and an index number. To simplify casting the data pointer in the notification, the following typedefs are defined:

```cpp
typedef ChangedValue<bool> ButtonChange;
typedef ChangedValue<std::string> LabelChange;
typedef ChangedValue<double> NumberDialerChange;
typedef ChangedValue<float> SliderChange;
```

### 4.3 Drawing Commands

The drawing namespace, draw, consists of a minimal wrapper around the OpenGL API, shape drawing routines, and vector-based text rendering.

**General Commands**

The draw rendering commands use the same syntax as OpenGL, but drop the “gl” prefix for clarity. The currently implemented commands can be found in the file glv_draw.h.
The following example shows how rendering commands would be used to draw a 3-D scene in a `View's` `onDraw()` method.

```cpp
void onDraw(){
    using namespace draw; // implicitly use draw:: in this scope
    push3D(w, h); // push into 3-D mode passing in width and height of view

    translate(tx, ty, tz); // transform model matrix
    rotate(rx, ry, rz); //
    scale(sx, sy, sz); //

    // draw axes of cartesian space
    begin(Lines);
    color(1, 0, 0); // set color to red
    vertex(0,0,0); vertex(1,0,0); // draw +x-axis
    color(0, 1, 0); // set color to green
    vertex(0,0,0); vertex(0,1,0); // draw +y-axis
    color(0, 0, 1); // set color to blue
    vertex(0,0,0); vertex(0,0,1); // draw +z-axis
    end();
    pop3D(); // pop out of 3-D space
}
```

**Text**

The `draw` namespace has a function for rendering simple text to the screen. The text renderer uses an internal fixed-width vector font with each character defined on an 8x11 unit grid. The cap lies at 0 units and the baseline at 8 units. In general, characters are rendered with the minimal number of vertices that does not sacrifice their readability and distinction from others. The text rendering mechanism is not meant to be comprehensive, but to be quick and easy without requiring dependencies on external libraries or font files.

![Figure 5: Default GLV vector font](image)

A text string can be rendered using one line of code:

```cpp
draw::text("Amazingly few discotheques provide jukeboxes.");
```

In this example, the text is drawn with its left edge at 0 and letter cap at 0. Text strings with new lines, `\n`, and tabs, `\t`, are also handled properly by the renderer.
4.4 Widgets

ValueWidget

ValueWidget is the base class for widgets that control one or more numerical values, such as sliders and buttons. It contains a one-dimensional array of values and an interval to which those values are restricted.

Sliders w(Rect(100,20), 8); // make a bank of 8 sliders
w.interval(100, 0); // set value interval to [0,100]
w.min(); // get lower bound of interval (-0)
w.max(); // get upper bound of interval (-100)
w.value(50, 0); // set slider 0 to 50
w.value(90, 1); // set slider 1 to 90
w.value(0); // get slider 0 value (=50)

For widgets having more than one value, there are methods for accessing specific widget elements.

Buttons w(Rect(100), 4,2); // make a 4x2 grid of buttons
w.size(); // get total number of elements (=16)
w.sizeX(); // get number of elements across x dimension (=4)
w.sizeY(); // get number of elements across y dimension (=2)
w.select(1,1); // select button at x,y position (1,1)
w.select(5); // select button at x,y position (5/4, 5 mod 4) = (0, 1)
w.selected(); // get last selected button (=5)

It is possible to attach variables to a ValueWidget that get updated whenever the widget changes value.

Slider2D w;
float x,y; // some variables to control
w.attachVariable(x, 0); // attach variable to the first widget value
w.attachVariable(y, 1); // attach variable to the second widget value
w.value(0.5, 0); // x is set to 0.5
w.value(0.1, 1); // y is set to 0.1

When variables are attached to a ValueWidget they will be polled from the GLV draw loop to see if they differ from the mapped to value in the widget. If the variable differs, then the widget will synchronize its value to the attached variable and send out any notifications to observers.

Label

A Label is a text string that is typically attached as a child to another view. By default, Labels do not render a background or border allowing them to ‘float’ on top of other views. Hit testing is also disabled by default preventing them from stealing focus from a parent view. Labels can also be specified to render vertically which can be useful for notating the y-axis of graphs.

Button

A Button is a widget that has two possible states- on or off. By default, a Button is toggleable meaning that its state changes when it is clicked on. A Button can also be made non-toggleable so that it becomes active on a MouseDown event and inactive on a MouseUp event. Button has two drawing function pointers for specifying which graphical symbols to use for on and off states.
Buttons

The Buttons widget is an extremely flexible N x M button array. It can be used to create menus, radio buttons, and button matrices, for example. The Buttons widgets can be either in mutually exclusive mode or not. When in mutually exclusive mode, only one button can be on at a time. Otherwise, any number of buttons can be on or off at a time.

![Buttons Examples](image)

**Figure 6: Button and Buttons**

FunctionPlot

The FunctionPlot object permits graphing of functions in one or two dimensions. It has two internal buffers for storing x and y coordinate data. If only one of these buffers is written to, then a 1-D graph is made. If both buffers are written to, then a 2-D graph is made. There is also a third color buffer that can be used for plotting additional dimensions. The range of the x and y axes can be custom set.

![FunctionPlot Examples](image)

**Figure 7: FunctionPlot**

NumberDialer

The NumberDialer allows one to treat each digit of a number as a dial. The number of digits in the integer and fractional parts is specified upon construction. The NumberDialer can also be specified to have a minimum or maximum value. The default amounts are the largest displayable values. When a digit is dragged up or down with the mouse, the number is incremented or decremented by an amount proportional to the place of the digit. The currently selected digit (indicated by a lightly colored box) can also be modified through the number keys on the keyboard. The sign of the number can be toggled by clicking it or by pressing the '+' key.
Slider

The Slider widget allows one to change a value by sliding a bar across the screen. Depending on its dimensions, the slider will automatically be displayed as vertical ($w < h$) or horizontal ($w \geq h$). The slider value is 0 at the left or bottom edge and 1 at the top or right edge. In its signed mode, the value is -1 at the left or bottom edge.

Clicking on the slider with the left mouse button will set its absolute position. Dragging with the left or right mouse button will increment the slider’s value. Normally, the amount the slider moves is in a one-to-one correspondence to the mouse cursor position. However, if both mouse buttons are held while dragging, the slider is incremented by a quarter of the distance the mouse moves.

Sliders

The Sliders widget is a group of several sliders. In general, it will be easier and more efficient to control a set of values using a single Sliders widget rather than multiple Slider widgets. The sliders can be displayed either horizontally or vertically. It also supports a special drag set mode where sliders can be set by dragging across the widget as if drawing a curve. Mouse interaction with individual sliders is the same as the Slider widget.

SliderRange

The SliderRange widget allows one to control the minimum and maximum values of an interval. The entire interval can be translated by dragging the bar. Clicking and dragging near the ends of the bar changes the associated extremum. Clicking on a blank region causes the whole interval to translate in the direction of the click.
Slider2D

The Slider2D widget is used to control two numeric values simultaneously, such as an x-y position. A knob indicates the current values of the slider. The slider values are 0 at the left or bottom edge and 1 at the top or right edge. Mouse interaction along each axis of Slider2D is the same as with the Slider widget.

![Slider2D](image)

Figure 11: Slider2D

SliderGrid

The SliderGrid widget is used to control two or more parameters either alone or in pairs. Each cell in the grid represents one permutation of parameter pairs. The pairs are controlled just like in Slider2D, with the exception of the cells along the diagonal. The diagonal cells allow exclusive control over individual parameters. The parameters are layed out on the grid with the first parameter at the bottom-left and the last parameter at the top-right. Within each cell, the slider values are 0 at the left or bottom edge and 1 at the top or right edge. Mouse interaction within cells is the same as with the Slider2D widget.

![SliderGrid](image)

(a) Three element SliderGrid  (b) Four element SliderGrid

Figure 12: SliderGrid

View3D

View3D allows a 3D scene to be rendered within a View. Custom drawing code is implemented by subclassing View3D and overriding the virtual onDraw3D() method. View3D has options for setting the near and far clipping planes and the field of view angle in the y direction. By default, depth testing is enabled and blending is disabled.
4.5 Layout

Placer

The Placer object is used to position a sequence of elements relative to each other, at absolute positions, or a combination of both. Placer holds relative increment factors and absolute increment amounts for both the x and y directions, thus making it an extremely flexible layout positioner.

In the simplest case, elements can be arranged so that their absolute positions are a fixed distance apart. This is done by using relative increment factors of zero and absolute increment amounts equal to the distance.

```plaintext
View top;
View v1(Rect(6)), v2(v1), v3(Rect(4)), v4(Rect(10,8));

// args: (absolute x-increment, absolute y-increment)
Placer placer(8, 0);
placer << v1 << v2 << v3 << v4;
```

This results in the arrangement:

Another use of Placer is to position a sequence of views with a fixed amount of padding between them. In this case, the relative increment factor is set to 1, while the absolute increment is set to the desired padding amount. The following example positions elements going east with a padding of 1.

```plaintext
View top; View v1(Rect(6)), v2(v1), v3(Rect(4)), v4(Rect(10,8));

// args: (parent view, flow direction, align place, initial x, initial y, padding)
Placer placer(top, Direction::E, Place::TL, 0,0, 1);
placer << v1 << v2 << v3 << v4;
```

This results in the arrangement:

In the previous example, the alignment was set to the top-left corner. By setting the alignment property of Placer, views can be aligned from different places.

Arrangement using center-left alignment:

Arrangement using bottom-left alignment:

Table

The Table object is used for doing general rectangular layouts on an N x M dimensional grid. A 2D arrangement string is used to specify how Views will be arranged when added to the table, starting from the top-left corner and going left-to-right, top-to-bottom. The arrangement string consists of single character codes that specify either existence of elements and their alignments or table cell structure (i.e. spanning, dimensions).
The element alignment codes are:

\[
\begin{array}{ccc}
p & ^q & \text{top-left} \quad \text{top-center} \quad \text{top-right} \\
< \times > & \text{center-left} \quad \text{center-center} \quad \text{center-right} \\
b & v & d \quad \text{bottom-left} \quad \text{bottom-center} \quad \text{bottom-right}
\end{array}
\]

The structural codes are:

- . empty region
- \(-\) span first leftward neighboring element rightward
- | span first upward neighboring element downward
- , end of row

The arrangement string makes it easy to specify complex layouts. The string can be written in a two-dimensional fashion to give a one-to-one visualization of the arrangement.

```cpp
const char * layout = ". x - x,"
"x x x -,"
"| x | . "
```

Table table(layout);
table << v1 << v2 << v3 << v4 << v5 << v6;
table.arrange();

This produces:

If the arrangement string is shorter than the number of Views added, then it will be repeated. This feature can be used to define a layout pattern using only a single row specification.

```cpp
Table table("><");
table << v1 << v2 << v3 << v4 << v5 << v6;
table.arrange();
```

This produces:
