Project 1: My SQL & Knowledge Discovery

MAT 255 - Winter 2021
Brenna Heffley

Introduction & Description:

For the first project I will be looking at inquisitions in the late out through earlier. Specifically, I will be looking at checkout time in days for the first book in the Twilight series by Stephenie Meyer, namely "Twilight". Published in 2005, the book is based in Forks, Washington around 100 miles away from Seattle. The data I am using comes from the Seattle Public Library with a full years of checkout and checkin data. Specifically, I would like to answer the following questions:

- Are there any observations that do not fit the rest of the data set?
- What is the average checkout time?
- How do the outliers influence the standard deviation?

I will address the above questions in my analysis below. This will include SQL codes, corresponding CSV outputs, descriptions, and visualizations.

SQL Library Stacks: Twilight Book

```
SELECT
    *
FROM
    stacks_2005_to_present
WHERE
    item_id = "Your item#"
    AND itemtype LIKE "%a%"
    AND checkout_year = "Year you checked out"
ORDER BY CHECKOUT_DATE;
```

Data & Data Records: stacks_2005_to_present

From the query, we get 1,927,035 rows returned. This means that the book Twilight has been checked out and returned a total of 8,065 times. This number is significant to use in the following assignments and data analysis.

Also, notice that each line is the item type of 'a004' which is Adult Fic/Book.

• Average time checked out in days:

First, I am going to aggregate the average time checked out per year.

```
SELECT
    checkout_year,
    AVG(time_to_sec(timediff(checkin, checkout)) / 86400) AS time_in
    FROM
        stacks_2005_to_present
    WHERE
        item_id = "Your item#"
        AND itemtype LIKE "%a%"
        AND checkout_year = "Year you checked out"
    GROUP BY checkout_year
ORDER BY checkout_year;
```

Data & Data Records:

avg_time_in_days_year	
checkout_year	**AVGtime_IN**
2005	14.6119
2006	20.0294
2007	21.0000
2008	16.4919
2009	21.1786
2010	19.0000
2011	18.0000
2012	20.0000
2013	19.0000
2014	19.0000
2015	18.0000
2016	18.0419
2017	19.0000
2018	20.0663
2019	18.0419
2020	19.0000
2021	19.0000
2022	37.9867
2023	19.0000
2024	19.0000

From the query, the number of books being checked out during 1970 is much clear. We know this cannot be accurate due to the nature of the database. However, 2020 has the highest average of 2021 days (2021 days) for the minimum number of days for checkout, and a 76 days avg in 5 of 6 outlier books. Also, 2020 and 2021 both contain those odd items of the average checkout time significantly. However, they are clearly outliers but due to a data entry error? I am going to investigate this further in the following assignments.

• Average & Standard Deviation Over all time

```
SELECT
    AVG(time_to_sec(timediff(checkin, checkout)) / 86400) AS time_in
    FROM
        stacks_2005_to_present
    WHERE
        item_id = "Your item#"
        AND itemtype LIKE "%a%"
        AND checkout_year = "Year you checked out"
    GROUP BY checkout_year
ORDER BY checkout_year;
```

Data & Data Records:

avg_stdev	
AVGtime_OUT	**STDDEVtime_OUT**
22.8391	24.512840061964940

The average amount of time for the first Twilight book was checked out for 22.84 days, or 22.84 days and the standard deviation is 24.51. This is the average and standard deviation that I will be using through the rest of my analysis to determine outliers in the dataset.

• Finding Outliers Using Z-Scores:

I will be detecting outliers using by detecting observations that are outside 3 standard deviations of the mean. Since it is impossible for a book to be checked out for a negative amount of time, I will only be concerned with outliers that are 3 standard deviations above the mean. I will be using the equation in the answer below to calculate using the STDDEVIN calculation in SQL's during the inference between the one and six data in number of days.

Data & Data Records:

num_outliers	
OutlierNum	**OUtOfOutlierRange**
not an outlier	7760
outlier	56

Based on the outcome for average and standard deviation, a checkout time of 70 (split is dictated as outlier if it is checked out for longer than 96 days. There are 56 outliers in the dataset. Also, I found that the first outlier was checked out in the year 2005 and the last outlier was checked out in the year 2021. This is a long the time period of 2005 to 2021.

• Collective Outliers:

I observed that a majority of the outliers are grouped together. Also, a lot of the data points on the scatter plot do not seem "too bad" or rather "not be outliers". This is because the data set contains books that are checked out for a long period of time. Therefore, I am going to look at the outliers that occur in a concentrated window. It's when the time points are considered as a collective that anomalous patterns are observed." Essentially, a group of outlier points are considered as collective outliers.

• Outlier Correlation with Movie Release?

Partial to Stephanie Meyer was introduced on November 5, 2005. The movie for this first book was released on November 17, 2008. Given how long it can take going to time the number of outliers by year of checkout to see if there are any patterns to observe here.

```
SELECT
    checkout_year, COUNT(outlierStatus)
FROM
    (SELECT
        item_id, DATEDIFF(checkin, checkout) AS time_OUT,
        CASE
            WHEN time_OUT >= 70 THEN 'outlier'
            ELSE 'not an outlier'
        END AS outlierStatus
    FROM
        stacks_2005_to_present
    WHERE
        item_id = "Your item#"
        AND itemtype LIKE "%a%"
        AND checkout_year = "Year you checked out"
    ORDER BY time_OUT DESC) AS outliers
WHERE
    outlierStatus = 'outlier'
GROUP BY checkout_year;
```

outliers by year

YEAR(ymd)	COUNT(OutlierStatus)
2005	2
2006	3
2007	3
2008	5
2009	14
2010	5
2011	4
2012	3
2013	1
2014	1
2021	1

Most of the outliers are checkouts occurring in 2009 and 2010. The highest number is seen in 2009 which is also the year that had the highest number of checkouts for the first book in the series. 2009-2010 is the time period in the movie that has been released to the general public and has been out for a few years.

Next, I will take a look closer at how long these checkouts were for. I will visualize the results for better clarity.

```
SELECT
    checkout_year,
    CASE
        WHEN time_OUT >= 70 THEN 'outlier'
        ELSE 'not an outlier'
    END AS outlierStatus,
    time_OUT
FROM
    (SELECT
        item_id, DATEDIFF(checkin, checkout) AS time_OUT,
        CASE
            WHEN time_OUT >= 70 THEN 'outlier'
            ELSE 'not an outlier'
        END AS outlierStatus
    FROM
        stacks_2005_to_present
    WHERE
        item_id = "Your item#"
        AND itemtype LIKE "%a%"
        AND checkout_year = "Year you checked out"
    ORDER BY time_OUT DESC) AS outliers
WHERE
    outlierStatus = 'outlier'
ORDER BY time_OUT DESC;
```

Data & Data Records: outliers_09_10_20.csv

Min	Not released
Q1	Around 21 days
Q2 Median	Around 28 days
Q3 Upper Fence	Around 35 days
Q3 Upper Avg Range - Out	Around 70 days
Q3 Upper Avg Range - In	Around 96 days

The graph shows the average checkout time for each year (outliers only!). 2009 has the highest average of 206.9 days! I also included the movie release date. Although the movie was very popular, the movie coming out in theaters brought a lot of fame to the storyline. The high average in 2009 can be a result of many people being drawn to the story line and checking out the book. They were drawn to the fandom, but never got a chance to read the book when it was first published.

Also, it is interesting to see that the 2020 and 2021 outliers are not as high as 2009. Is the fandom dead now? No, I don't think so. You can marvel the time since the period ends, but as far as I know our database does not register renewals. Below is their policy on late/lost items:

"When an item is 21 days overdue we consider it lost and charge you for the replacement cost. We remove the charge for replacement when you return the item."

The website also states, "We will temporarily suspend your Library account when an item is 14 days overdue."

Therefore, I am going to look at the Q3 Upper Fence for the Average Upper Range. This is not much of a baseline for looking out as most for long periods of time. The people who checked out the book Twilight for an extended period of time likely did not face any financial burden. Rather, their library card was cut off as we will study this concept in Project 2.

[Reference Link 1]

Also, I am curious about how the movies affected the set of outliers in checkout time. I decided to investigate the popularity in checkouts of the first book series. Those were the ones that were out during the choice of outliers that we are observing. Below is a query, data table, and visualization displaying results.

```
SELECT
    checkout_year,
    CASE
        WHEN time_OUT >= 70 THEN 'outlier'
        ELSE 'not an outlier'
    END AS outlierStatus,
    time_OUT
FROM
    (SELECT
        item_id, DATEDIFF(checkin, checkout) AS time_OUT,
        CASE
            WHEN time_OUT >= 70 THEN 'outlier'
            ELSE 'not an outlier'
        END AS outlierStatus
    FROM
        stacks_2005_to_present
    WHERE
        item_id = "Your item#"
        AND itemtype LIKE "%a%"
        AND checkout_year = "Year you checked out"
    ORDER BY time_OUT DESC) AS outliers
WHERE
    outlierStatus = 'outlier'
ORDER BY time_OUT DESC;
```

Data & Data Records: Vampire_checkouts.csv

It is not that the checkouts for the movie were the most popular during 2009, 2010, and 2011. That is a very dusty of the 3 year cluster we see of the checkouts. Also, I am curious about the 2020 and 2021 outliers. Is it because of the movie? Is it because of the pandemic? Is it because the physical copy was the only option? Is it because the Check Out Limit Lifted checkouts at the ATL, or is that why we have a popular item to checkout.

• Average & Standard Deviation Removing Outliers:

Now, I will run a query calculate the Average and Standard Deviation of the population (with the outliers removed). This will show how the outliers have affected the origin statistics that we either used in my previous assignments.

```
SELECT
    AVG(time_OUT), STDDEV(time_OUT)
FROM
    (SELECT
        item_id, DATEDIFF(checkin, checkout) AS time_OUT,
        CASE
            WHEN time_OUT >= 70 THEN 'outlier'
            ELSE 'not an outlier'
        END AS outlierStatus
    FROM
        stacks_2005_to_present
    WHERE
        item_id = "Your item#"
        AND itemtype LIKE "%a%"
        AND checkout_year = "Year you checked out"
    ORDER BY time_OUT DESC) AS outliers
WHERE
    outlierStatus = 'not an outlier';
```

Data & Data Records:

stats_not_an_outlier	
AVGtime_OUT	**STDDEVtime_OUT**
21.9836	15.5994260221726

With the outliers removed, the **average was 21.84** and the **Standard Deviation was 16.01**. Therefore, the average did not change much when removing the outliers. However, the standard deviation decreased significantly. This means that the fat/extreme of the sample has decreased, which makes sense.

• Why are the outliers in checkout time occurring?

Below are 2 possible hypothesis that I have for why there are 56 outliers in the sample for checkout time. Recall that these outliers are checkouts period that are greater than 70 days.

>> Movie Correlation:

The outliers occurred at the same time that the movie checkout spikes. Then, may be some correlation between long checkout times and movies checkouts (popularity) of the movie.

>> 2009 Library Shutdown:

In 2009, from Monday, August 3 to Saturday, September 5, the Seattle Public Library shut down. The shut down was due to city-wide budget cuts. In response to the shutdown, the Seattle Library system was ranked the 2nd busiest city by 2009. The 2009 was forced to close all of the locations for 5 weeks. During the closure, the books could be checked out and returned even by book drop off. Furthermore, the website was non-accessible and there was no access to the online catalog to search for books during the shutdown.

[Reference Link 2]

Therefore, I am going to look at the number of checkouts per year in the year with the maximum number of outliers (2009). It is a possibility that visitors checked out their books sometime in 2008 and were unable to return during the week of the shut down. Furthermore, they were forced to return them further in the year. Therefore, they were charged a late penalty. It is plausible that this reason caused/created the 206 overtime to when they are return their items.

Query & Results:

>> Library Popularity:

I am going to query for the number of checkouts and checkins (return) per year. This will measure popularity at the NPL over the years.

```
SELECT
    checkout_year, COUNT(checkout_year), 1)
FROM
    stacks_2005_to_present
WHERE
    item_id = "Your item#"
    AND itemtype LIKE "%a%"
GROUP BY checkout_year
ORDER BY checkout_year;
```

Data & Data Records: Checkouts_YR.Seattle

num_checkouts_yearly	
checkout_year	**COUNT(checkout_year)**
2005	8,073,000
2006	8,073,000
2007	8,056,000
2008	8,056,000
2009	7,813,000
2010	7,813,000
2011	7,813,000
2012	7,585,000
2013	8,016,000
2014	8,016,000
2015	8,016,000
2016	8,016,000
2017	8,016,000
2018	8,016,000
2019	8,016,000
2020	4,008,000
2021	4,008,000
2022	4,008,000
2023	4,008,000
2024	4,008,000

```
SELECT
    checkin_year, COUNT(checkin_year), 1)
FROM
    stacks_2005_to_present
WHERE
    item_id = "Your item#"
    AND itemtype LIKE "%a%"
GROUP BY checkin_year
ORDER BY checkin_year;
```

Data & Data Records: Checkins_YR.Seattle

num_checkins_yearly	
checkin_year	**COUNT(checkin_year)**
2005	7,194,892
2006	7,194,892
2007	10,202,938
2008	10,202,938
2009	10,147,828
2010	8,178,750
2011	8,178,750
2012	8,974,127
2013	8,974,127
2014	9,287,000
2015	8,883,539
2016	8,883,539
2017	8,883,539
2018	8,883,539
2019	8,883,539
2020	4,441,768
2021	2,868,979
2022	4,441,768
2023	4,441,768
2024	4,441,768

From the above two query outputs, it is seen that 2009 has the highest number of checkouts and checkins followed by 2008 and 2010. This is the same result that I found when looking at the outliers. Therefore, the popularity of the library system is not the driving factor for the outliers. However, the outliers distribution and the checkout distributions do not follow the same trend overall.

It is likely that the outcome of the outliers' occurrences is not solely one of these. Also a combination of the above 3 hypotheses.

• Moving forward, how do I think we can stop these outliers from occurring?

The outliers that have been found have 3 common factors that can be taken to stop them from occurring. I think that the NPL would need to implement a stronger policy for long borrow times. Not much has happen if an item or checked out for such a long period of time. If something where were to be put into place, then the outliers would be reduced.

• Preparing for 3D Visualization:

In preparation for the remainder of the course, I want to run the research above to produce data that can be used to create a 3D visualization in the future. This visualization will have three axis that will be from 3 columns. Below are the 3 columns that I will query for using MySQL:

1. total (Date of checkout from NPL) - axis provider
2. Avg_time_out (Average time checked out) - axis provider
3. OutlierStatus (outlier or not an outlier) - axis provider
4. Vector Status (Category # per this) axis based on acquisition date) - axis provider

Note: the vector status provided by NPL will be removed. Labeling each individual will

```
SELECT
    checkout_year,
    CASE
        WHEN time_OUT >= 70 THEN 'outlier'
        ELSE 'not an outlier'
    END AS outlierStatus,
    time_OUT
FROM
    (SELECT
        item_id, DATEDIFF(checkin, checkout) AS time_OUT,
        CASE
            WHEN time_OUT >= 70 THEN 'outlier'
            ELSE 'not an outlier'
        END AS outlierStatus
    FROM
        stacks_2005_to_present
    WHERE
        item_id = "Your item#"
        AND itemtype LIKE "%a%"
        AND checkout_year = "Year you checked out"
    ORDER BY time_OUT DESC) AS outliers
WHERE
    outlierStatus = 'outlier'
ORDER BY time_OUT DESC;
```

Data & Data Records: 3D_Visualization.csv

There is not much to analyze from the output csv. I just wanted to practice writing such query in preparation for future projects.

Observations Based on Results:

In conclusion, the project allowed me to detect outliers from a sample in the NPL data base. I learned about a certain type of outliers, collective outliers, that I was not aware of before. Also, I learned how to detect outliers through a method I mentioned why and when these outliers occurred as checkout period of time. Finally, I learned how to create a query that can be used for future projects. Overall, I enjoyed working with the data provided by the Seattle Public Library and Brenna's popularity showing the many times checked out. I wished the project for creating a software that can be used for 3D visualization.
